

Chromosome :-

Chromosomes are thread-like structures located inside the nucleus of animal and plant cells.

Each chromosome is made of protein and a single molecule of deoxyribonucleic acid (DNA)

↳ Contains many gene
[DEPTH OF BIOLOGY]

↓
a section of DNA that holds the instruction for a protein.

↳ Human have 23 pairs.

DNA is spiraling chain like molecule
↓ [DEPTH OF BIOLOGY]

made up of 4 different type of Nucleotide.

which are wrapped with a string like
structure.

[DEPTH OF BIOLOGY]

Chromatin :-

[DEPTH OF BIOLOGY]

↳ Nucleosome → Beads on string.

↳ Further condense form of chromatin
known as chromosome.

[DEPTH OF BIOLOGY]

↓
Only see during cell division
(we see in the prophase)

Nucleosome = 8 Histone

Gene :- Fragment of DNA which control our character.

↳ During gene expression, the DNA is first copied into RNA.

[DEPTH OF BIOLOGY]

DNA :-

↳ Structure discovered by Watson & Crick.

↳ Double Stranded.

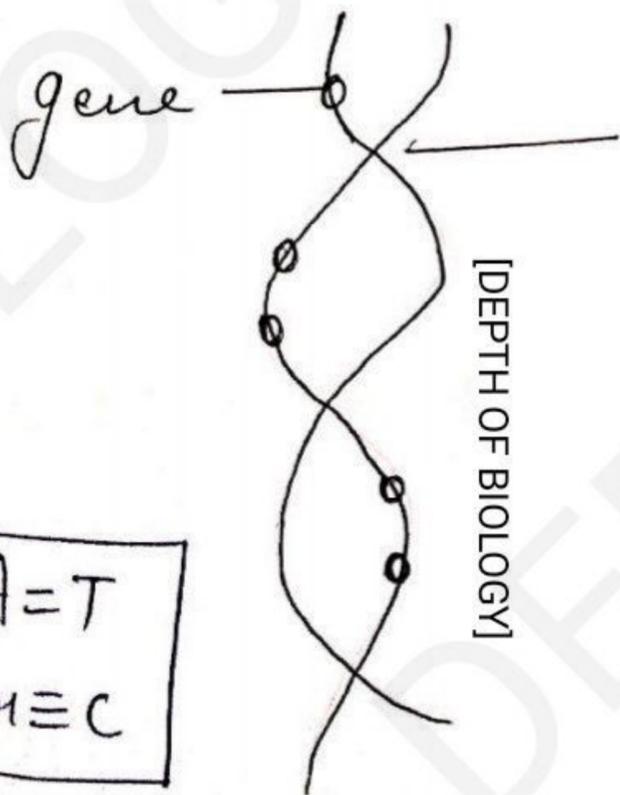

↳ 500 million base pairs.

↳ Deoxyribonucleic acid → DNA fingerprinting

[DEPTH OF BIOLOGY]

↳ Antiparallel Strand.

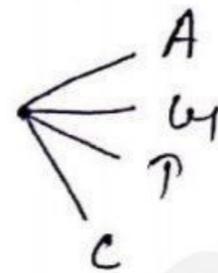

↳ 2-8 cm.

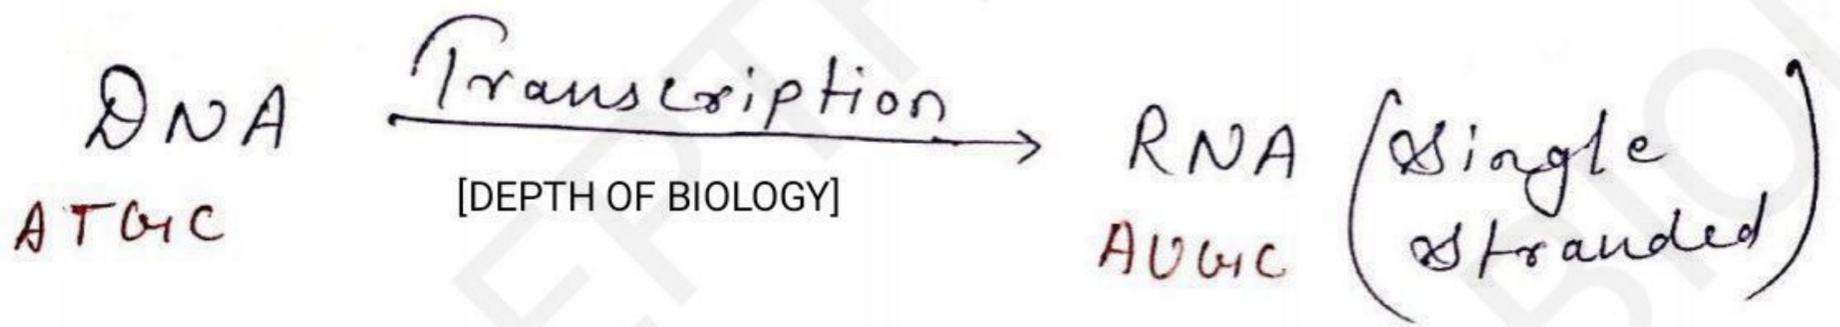

Composed of

Phosphate group

A=T
G=C

Protein Synthesis :-

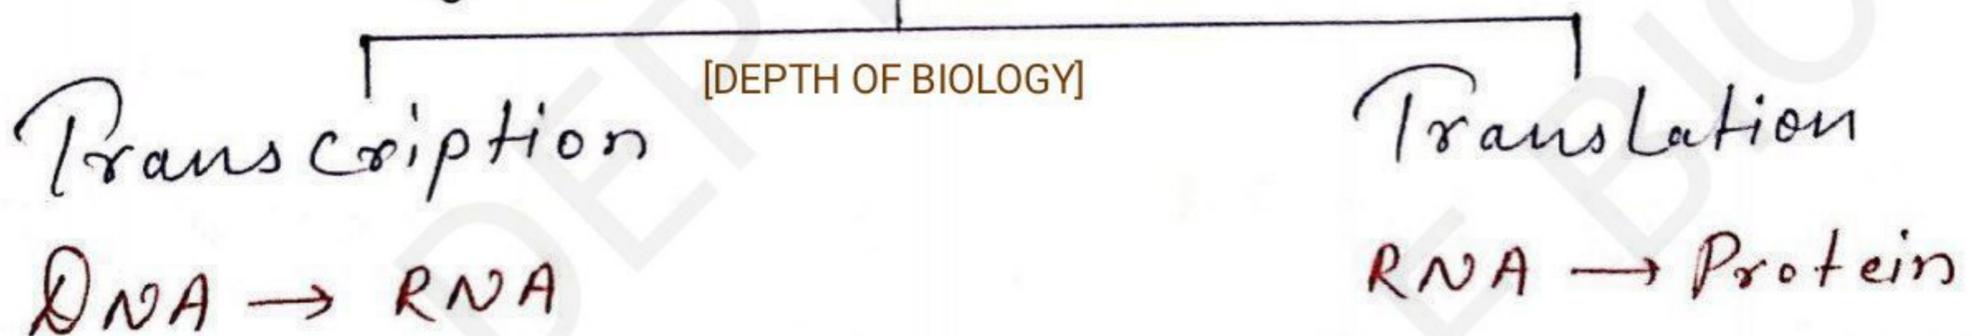

Protein synthesis is the process in which cells make proteins.

It occurs in two stages: transcription and translation. Transcription is the transfer of genetic instructions in DNA to mRNA in the nucleus. [DEPTH OF BIOLOGY]

It includes three steps: initiation, elongation, and termination.

↳ RNA plays role in protein synthesis.

Protein synthesis has two main steps -

▶ In the process of transcription (RNA Polymerase) required.

It connects Complementary RNA Base to DNA.

- This RNA base are bonded together to form a single stranded mRNA.

[DEPTH OF BIOLOGY]

This mRNA go out of the nucleus into cytoplasm.

And attach to a Ribosome.

[DEPTH OF BIOLOGY]

↳ Made up of rRNA.

↳ It makes protein.

Now,

Ribosome undergo next translation.

⇒ In cytoplasm tRNA molecule available

[DEPTH OF BIOLOGY]

They carry amino acid on them.

monomer for protein

[DEPTH OF BIOLOGY]

So, we need this amino acid.

↳ All tRNA looking for complementary bases

When they find complementary bases on the mRNA

They transfer their amino acid.

[DEPTH OF BIOLOGY]

⊕ tRNA now read the codon.

with UAC Anticodon → Pair with

Complementary AUG Codon.

Start Codon

[DEPTH OF BIOLOGY]

and it transfer its amino acid

↳ called methionine

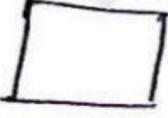

⊕ tRNA leave

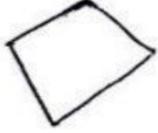

This amino acid hold together by peptide bond. and protein synthesis occur.
